NEW MEASURES OF DIVERSITY

Manzoor Ahmad

ABSTRACT

The problem of measuring diversity within populations and dissimilarity or similarity between populations has been extensively treated in the literature. In this context a general procedure called Analysis of Diversity has been outlined and examined by C.R. Rao in a series of papers.

In this paper we proposes three new measuers of diversity and study related inference problems. Denote by S^k the simplex $S^k = \{\pi: \pi = (\pi_1, \dots, \pi_k)^{\dagger}, \pi_j \geq 0, \Sigma \pi_j = 1\}$. Then the proposed measures are of the form: $H_m(\pi) = 1 - a \sum_{m = 1}^{\infty} \pi_j \phi_m(\pi_j), m = 1, 2, 3$ where $\phi_1(x) = (1+k^{-1}-x)^{-\gamma}$, $\gamma \geq 0$, $\phi_2(x) = (2-k^{-\gamma}-x^{\gamma})^{-1}$, $\gamma \geq 0$, $\phi_3(x) = (a_3+(1-x)^{\gamma})^{-1}$, $0 < \gamma \leq 1$, and the a's are suitable normalizing constants. Estimation of $H_m(\pi)$, derivation of the penalty function and cross entropy and the problem of testing independence have been treated. Asymptotic distributions of relevant test statistics are indicated.

1. INTRODUCTION

The problem of measuring diversity within populations and dissimilarity or similarity between populations has been extensively treated in the literature. This problem arises in a wide variety of domains; linguistics (Horvath, 1963; Zinger, 1982; Greenberg, 1956; Guirand, 1959; Herdan, 1964, 1966; Yule, 1944; Savchue, 1964), sociology (Agresti and Agresti, 1978), biology (Sokal and Sneath, 1963; Pielou, 1975; Patil and Taillie, 1979), anthropology (Rao, 1971a, 1977b), to mention a few. An extensive bibliography of papers on measures of diversity and their applications can be found in Denmis et al (1979) and Patil and Taillie (1982).

Diversity within populations and dissimilarity between populations have been measured and interpreted differently. The choice of a diversity measure essentially depends on the context of a problem, however any diversity measure satisfying certain basic conditions can be used for partioning the total variability into a number of additive components, each of which can be used to test a certain null hypothesis or estimate a component of the variability. Rao (1982,a,b) outlined a general procedure called Analysis of Diversity (ANODIV) which is similar to the Analysis of Variance (ANOVA) for quantitative data. In this direction Light and Margolin (1971, 1974), Anderson and Landis (1980) have studied the Gini-Simpson index of diversity while Nayak (1984) has extended their results for Quadratic Entropy introduced by Rao (1982,b,c).

Following the general procedure of Rao (1982,a,b) any function H defined on the simplex $S^k = \{\pi: \ \pi = (\pi_1, \dots, \pi_k)'; \ \pi_j \ge 0, \ \Sigma \pi_j = 1\}$ of the Euclidean space R^k , is said to be a diversity measure if it satisfies the following conditions

- (a) $H(\pi) \ge 0$, '=0', if and only if $\pi_i = 1$ for some j and $\pi_i = 0$, $\forall j' \ne j$
- (b) $H(\pi) \le 1$ and '=1' if and only if π is a uniform distribution i.e. $\pi_1^{-\pi} 2^{-\dots -\pi} k^{-\frac{1}{k}}$
- (c) $H(\pi)$ is concave in π on S^k .

While condition (a) is natural and (b) is standard normalization, the condition (c) fulfills the requirement that the diversity in a weighted mixture of populations should not be smaller than the weighted sum of diversitites within the individual populations. Gini-Simpson index of diversity, quadratic entropy of Rao, Shannon's entropy, a-degree entropy of Renyi (1961), a-degree entropy of Havrda and Charvat (1956), among others, satisfy conditions (a), (b) and (c). (See Nayak (1985a)).

We consider three measures which are of the form; $\forall \pi \in S^k$

(1.1)
$$H_{m}(\pi) = 1 - a_{m} \sum_{j=1}^{k} \pi_{j} \phi_{m}(\pi_{j}), \quad m = 1, 2, 3$$

where

(1.2)
$$a_1 = k^{-\gamma}, \ \phi_1(x) = (1 + k^{-1} - x)^{-\gamma}, \ \gamma \ge 0$$

(1.3)
$$a_2 = 1 - k^{-\gamma}, \ \phi_2(x) = (2 - k^{-\gamma} - x^{\gamma})^{-1}, \ \gamma \ge 0$$

(1.4)
$$a_3 = (1-k^{-1})^{\gamma}, \phi_3(x) = (a_3 + (1-x)^{\gamma})^{-1}, 0 < \gamma \le 1.$$

These functions vanish only at the vertices e_j , $j=1,2,\ldots,k$ of S^k ; where the probability vector e_j represents a multinomial distribution whose j^{th} cell has cell frequency one and others zero. In section 2, we have shown that $H_1(\pi)$ is concave for $\gamma \geq 0$, $H_2(\pi)$ for $\gamma \geq 1$ and $H_3(\pi)$ for $0 < \gamma \leq 1$. Further, $\Psi \pi \in S^k$

(1.5)
$$H_m(\pi) \ge 0, m = 1,2,3$$

follows from the concavity of H_m since $\pi = \sum_{j=1}^k \pi_j e_j$, and $\Sigma \pi_j = 1$. We have also shown in section 2 that these measures take their maximum value at $\pi = (1/k, 1/k, ..., 1/k)$, the most spread multinomial population. Define

(1.6)
$$H_{m}^{0} = \max_{\pi \in S^{k}} H_{m}(\pi) = 1 - a_{m} \phi_{m}(\frac{1}{k}).$$

Then we have

(1.7)
$$H_1^0 = (k^Y - 1)/k^Y, \quad Y > 0$$

$$H_2^0 = H_3^0 = 1/2.$$

Further, since these functions are symmetric in (π_1, \dots, π_k) , they turn out to be Schur-concave which is indeed a desirable property for measuring variability in a multinomial population. With such measures, the more spread-out the population the more diverse it turns out to be.

In section 3 we have treated the problem of estimating the diversity of a multinomail population, based on the measure H_m ; m=1,2,3.

Derivation of the penalty function(Haberman (1982)) and cross entropy

(Rao (1982b)) for each of the proposed measures and the problem of testing independence has been treated in section 4.

2. CONCAVITY OF THE MEASURES H_m ; m = 1,2,3

From (1.1) it is obvious that the concavity of $H_m(\pi)$ would follow from the convexity of

(2.1)
$$I_{\mathbf{m}}(\pi) = \sum_{j=1}^{k} \pi_{j} \phi_{\mathbf{m}}(\pi_{j}); \quad \mathbf{m} = 1,2,3.$$

While proving their convexity, the functions I_m can be treated, without loss of generality, as functions of $\pi_1, \pi_2, \dots, \pi_{k-1}$ and

$$\pi_{k} = 1 - (\pi_{1} + \ldots + \pi_{k-1}); \quad \pi \in S^{k}.$$

2a. Convexity of $I_1(\pi)$

Since

$$I_1(\pi) = \sum_{j=1}^k \pi_j (1+k^{-1}-\pi_j)^{-\gamma} = \sum_{j=1}^k \pi_j n_j^{-\gamma}$$
 (say)

it follows that

(2.2)
$$\frac{\partial}{\partial \pi_{j}} I_{1} = \eta_{j}^{-\gamma} + \gamma \pi_{j} \eta_{j}^{-\gamma-1} - \{ \eta_{k}^{-\gamma} + \gamma \pi_{k} \eta_{k}^{-\gamma-1} \},$$

$$\frac{\partial^{2}}{\partial \pi_{j}^{2}} I_{1} = \tau_{j} + \tau_{k}, \quad 1 \leq j \leq k-1$$

$$\frac{\partial^{2}}{\partial \pi_{j}^{2}} I_{1} = \tau_{k}, \quad 1 \leq j' \leq k-1, \quad j' \neq j$$

where

$$\tau_{t} = \gamma \eta_{t}^{-\gamma-2} [2(1+k^{-1}) + (\gamma-1)\pi_{t}]$$

and

$$\eta_{t} = 1 + k^{-1} - \pi_{t}$$

For a given vector $\underline{\mathbf{d}} = (\underline{\mathbf{d}}_1, \dots, \underline{\mathbf{d}}_p)'$, let $\underline{\mathbf{D}}_{\underline{\mathbf{d}}}$ denote a diagonal matrix with elements $\mathbf{d}_1, \mathbf{d}_2, \dots, \mathbf{d}_p$. Now, the matrix $\nabla^2 \mathbf{I}_1$ of second order derivatives of \mathbf{I}_1 takes form

(2.3)
$$\nabla^2 I_1 = D_{\tau} + \tau_{k} 11^{-1}$$

with

$$\tau = (\tau_1, \tau_2, \dots, \tau_{k-1}),$$

which is certainly positive definite for $\Psi \gamma \geq 0$.

2b. Convexity of $I_2(\pi)$

In this case

(2.3)
$$I_{2}(\pi) = \sum_{j=1}^{k} \pi_{j} (\beta - \pi_{j}^{\gamma})^{-1}$$

where $\beta = 2-k^{-\gamma}$, and straightforward computations yield

(2.4)
$$\frac{\partial}{\partial \pi_{\mathbf{i}}} \mathbf{I}_{2} = (\beta - \pi_{\mathbf{j}}^{\Upsilon})^{-1} + \gamma \pi_{\mathbf{j}}^{\Upsilon} (\beta - \pi_{\mathbf{j}}^{\Upsilon})^{-2}$$
$$- (\beta - \pi_{\mathbf{k}}^{\Upsilon})^{-1} - \gamma \pi_{\mathbf{k}}^{\Upsilon} (\beta - \pi_{\mathbf{k}}^{\Upsilon})^{-2},$$
$$\frac{\partial^{2}}{\partial \pi_{\mathbf{j}}^{2}} \mathbf{I}_{2} = \theta_{\mathbf{j}} + \theta_{\mathbf{k}}, \quad 1 \leq \mathbf{j} \leq \mathbf{k} - 1$$

and

$$\frac{\partial^2}{\partial \pi_j, \partial \pi_j} I_2 = \theta_k, 1 \le j' \le k-1; j' \ne j,$$

where

$$\theta_{t} = (\beta - \pi_{t}^{\gamma})^{-3} \{ \gamma (1+\gamma) \pi_{t}^{\gamma-1} (\beta - \pi_{t}^{\gamma}) + 2 \gamma^{2} \pi_{t}^{2\gamma-1} \}.$$

Hence,

(2.5)
$$\nabla^{2}I_{2} = D_{\theta} + \theta_{k-1}^{11}$$

with

$$\theta = (\theta_1, \theta_2, \dots, \theta_{k-1}),$$

is positive definite for $\gamma > 0$.

2c. Convexity of $I_3(\pi)$

Note that

(2.6)
$$I_{3}(\pi) = \sum_{i=1}^{k} \pi_{i} (b + \tilde{\pi}_{i}^{Y})^{-1}$$

where $b = (1-k^{-1})^{\gamma}$ and $\bar{\pi}_{j} = 1-\pi_{j}$, and

(2.7)
$$\frac{\partial}{\partial \pi_{j}} I_{3} = (b + \tilde{\pi}_{j}^{\gamma})^{-1} + \gamma \pi_{j} \tilde{\pi}_{j}^{\gamma-1} (b + \tilde{\pi}_{j}^{\gamma})^{-2}$$

$$- (b + \tilde{\pi}_{k}^{\gamma})^{-1} - \gamma \pi_{k} \tilde{\pi}_{k}^{\gamma-1} (b + \tilde{\pi}_{k}^{\gamma})^{-2}$$

$$\frac{\partial^{2}}{\partial \pi_{j}^{2}} I_{3} = \delta_{j} + \delta_{k}, \quad 1 \leq j \leq k-1$$

$$\frac{\partial^{2}}{\partial \pi_{j}^{2}} \tilde{\pi}_{j}^{2} I_{3} = \delta_{k} \quad 1 \leq j' \leq k-1, \quad j' \neq j$$

with

$$\delta_{t} = \gamma (2 - (1 + \gamma) \pi_{t}) \tilde{\pi}_{t}^{\gamma - 2} (b + \tilde{\pi}_{t}^{\gamma})^{-2}$$

$$+ 2 \gamma^{2} \pi_{t} \tilde{\pi}_{t}^{2 \gamma - 2} (b + \tilde{\pi}_{t}^{\gamma})^{-3}.$$

Hence

こうしゅう しんしんし はきご かいかい かずなり あてんしん しんしゃ

(2.8)
$$\nabla^{2}I_{3} = D_{\delta} + \delta_{k_{--}}^{11},$$

where elements of D_{δ} are $(\delta_1, \dots, \delta_{k-1})$, is p.d iff $0 < \gamma \le 1$.

2d. Maxima's of the Functions $H_{m}(\pi)$; m=1,2,3

Critical points of $H_{m}(\pi)$ for m=1,2,3, are solutions of the system of equations

(2.9)
$$\frac{\partial}{\partial \pi_{j}} H_{\mathbf{m}}(\pi) = -\frac{\partial}{\partial \pi_{j}} I_{\mathbf{m}}(\pi) = 0; \quad j = 1, 2, ..., k-1.$$

These equations, when m=1, are of the form, for j=1,2,...,k-1

$$\eta_{j}^{-\gamma} + \gamma (1+k^{-1}-\eta_{j}) \eta_{j}^{-\gamma-1} = k^{*}(const.)$$

Hence one can easily argue that the solutions must satisfy the condition

(2.10)
$$\eta_1 = \eta_2 = \dots = \eta_{k-1}$$

or equivalently

$$\pi_1 = \pi_2 = \dots = \pi_{k-1} = \frac{1}{k}$$

since the constant k^* is the value of the l.h.s. evaluated at n_k . Through analogous arguments, so turns out to be the case with $H_2(\pi)$ and $H_3(\pi)$.

3. ESTIMATION OF $H_m(\pi)$; m = 1,2,3

For inference problem, it is essential to estimate a measure of diversity $H(\pi)$. A popular estimate based on sample proportions p_1, p_2, \ldots, p_k would be $H(\hat{\pi})$ where $\hat{\pi}_j = p_j, \forall_j$. This is also the maximum likelihood estimator of $H(\pi)$ (Zehna (1966)). A Taylor series expansion of $H(\hat{\pi})$ around π allows us to compute the asymptotic variance of $H(\hat{\pi})$. To do so we first express $F_m(\hat{\pi})$ as

(3.1)
$$H_{\mathbf{m}}(\hat{\pi}) = 1 - \sum_{j=1}^{k} \psi_{\mathbf{m}}(\hat{\pi}_{j})$$

with

$$\psi_{m}(x) = a_{m}x\phi_{m}(x), m = 1,2,3$$

and treat H_{m} as a function of (k-1) free variables $\pi_{1}, \pi_{2}, \dots, \pi_{k-1}$ with $\pi_{k} = 1 - \sum_{j=1}^{k-1} \pi_{j}$, $\pi_{j} \ge 0$ for $j = 1, 2, \dots, k$, i.e. $H_{m}(\pi_{1}, \pi_{2}, \dots, \pi_{k-1}) = 1 - \sum_{j=1}^{k-1} \psi_{m}(\pi_{j}) - \psi_{m}(\pi_{k})$. Then

since $\frac{\partial}{\partial \pi_j} \pi_k = -1$, $\forall j$, and $\Sigma \hat{\pi}_j = \Sigma \pi_j = 1$. Now we can see easily that the asymptotic variances of $H_m(\hat{\pi})$, denotes by $\tilde{\sigma}_m^2$, is the variance of the linear combination k $\sum_{j=1}^{k} d_{mj} \hat{\pi}_j$ where

(3.3)
$$d_{mj} = \frac{\partial}{\partial \pi_{j}} \psi_{m}(\pi_{j}), \quad j = 1, 2, ..., k$$

$$= a_{m} \{ \phi_{m}(\pi_{j}) + \pi_{j} \frac{d}{d\pi_{j}} \phi_{m}(\pi_{j}) \}.$$

It follows that, for m=1,2 and 3, the asymptotic variance of the estimator $H_m(\pi)$ of the diversity measure $H_m(\pi)$ is

(3.4)
$$n\tilde{\sigma}_{m}^{2} = \sum_{j=1}^{k} \pi_{j} d_{mj}^{2} - \left\{ \sum_{j=1}^{k} \pi_{j} d_{mj} \right\}^{2}.$$

The sequences $\{d_{1j}\}_{j=1}^k$, $\{d_{2j}\}_{j=1}^k$ and $\{d_{3j}\}_{j=1}^k$ corresponding to $\tilde{\sigma}_1^2$, $\tilde{\sigma}_2^2$ and $\tilde{\sigma}_3^2$ respectively are

(3.5)
$$d_{1j} = a_1 (1+k^{-1}-\pi_j)^{-\gamma-1} \{1+k^{-1}+(\gamma-1)\pi_j\},$$

$$d_{2j} = a_2 (2-k^{-\gamma}-\pi_j^{\gamma})^{-2} \{2-k^{-\gamma}+(\gamma-1)\pi_j^{\gamma}\}$$

an d

$$d_{3j} = a_3 \{ (1-k^{-1})^{\gamma} + (1-\pi_j)^{\gamma} \}^{-2} \{ (1-k^{-1})^{\gamma} + (1+(\gamma-1)\pi_j)^{\gamma} (1-\pi_j)^{\gamma-1} \},$$

$$j = 1, 2, ..., k.$$

Remark. Note that $n\bar{\sigma}_{m}^{2}$ is equal to the variance of a random variable D_{m} which takes the value d_{mj} with probability π_{j} , $j=1,2,\ldots,k$.

Case $\gamma = 1$

Each of the diversity measures $H_{m}(\pi)$, m=1,2 or 3, can be seen as a family of measures since it depends on a parameter of our choice γ . Any choice of γ within the range of values for which $H_{m}(\pi)$ remains concave would lead to a specific measure. In practice as we will see in the sequal the choice of γ would depend upon the nature

of the problem. However the choice $\gamma=1$ should be emphasized since in this case H_m 's take a simpler form. Define the diversity measure G_m as

(3.6)
$$G_{m}(\pi) = H_{m}(\pi) \text{ with } \gamma = 1.$$

Then

をおけれたという。 ではないないが、 ではないない。

(3.7)
$$G_{1}(\pi) = 1 - k^{-1} \sum_{j=1}^{k} \pi_{j} (1 + k^{-1} - \pi_{j})^{-1},$$

$$G_{2}(\pi) = G_{3}(\pi) = 1 - (1 - k^{-1}) \sum_{j=1}^{k} \pi_{j} (2 - k^{-1} - \pi_{j})^{-1}$$

and the variances of the estimators $G_1(\hat{\pi})$ and $G_2(\hat{\pi})$ respectively are

(3.8)
$$n\tilde{\sigma}^{2}[\hat{G}_{1}] = k^{-2}(1+k^{-1})^{2}\sum_{j}\pi_{j}\{(1+k^{-1}-\pi_{j})^{-2}-\sum_{j}\pi_{j}(1+k^{-1}-\pi_{j})^{-2}\}$$

and

$$n\tilde{\sigma}^{2}[\hat{G}_{2}] = (1-k^{-1})(2-k^{-1})\sum_{j} \{(2-k^{-1}-\pi_{j})^{-2} - \sum_{j} \pi_{j}(2-k^{-1}-\pi_{j})^{-2}\}.$$

4. DECOMPOSITION AND TEST OF INDEPENDENCE

Consider a population P of a nominal random variable Y that assumes the integral values j, $1 \le j \le k$, which is being viewed as a mixture of r populations P_1, P_2, \ldots, P_r of Y identified according to r discrete levels of a factor X of some interest. Let $\pi_k = (\pi_{k1}, \ldots, \pi_{kj}, \ldots, \pi_{kj})'$ be the probability vector of Y for the population P_k , and λ_k be the mixing weight of π_k for the overall population P, $\lambda_k \ge 0$, $k = 1, 2, \ldots, r$, $\Sigma \lambda_k = 1$. Hence Y is assumed to follow a multinomial distribution whose probability vector π , is the mixture $\sum_{k=1}^{r} \lambda_k \pi_k$. Based on the data classified in the above fashion, we are usually intereseed in a problem of prediction or testing a hypothesis of independence or testing a hypothesis $H_0: \pi_1 = \pi_2 = \ldots = \pi_r$. Such inference problems are handled through the analysis of Diversity (ANODIV).

In this regard the following decomposition, due to Rao (1982,a,b), is most natural;

$$(4.1)^{*} \qquad H(\pi_{*}) = \Sigma \lambda_{\ell} H(\pi_{\ell}) + J_{H}(\{\lambda_{\ell}\}, \{\pi_{\ell}\}).$$

The component $\Sigma \lambda_{\ell} H(\pi_{\ell})$ is the average diversity within the populations, and the second term designated as "Jensen difference", defined by subtraction, represents the diversity between populations. The concavity of H ensures that $J_{H} \geq 0$. An alternative but similar decomposition, which provides an interpretation of J_{H} , can be obtained through the concept of 'Penalty function' associated with a diversity measure. (Rao and Nayak (1985).)

Let $\Delta(j,\pi^*)$ be the penalty (or the loss) to be incurred in a probabilistic prediction if a probability vector π^* is used for prediction and the true category is j. Then expected penalty for using π^* is $\Sigma\pi_j\Delta(j,\pi^*)$. If a diversity measure H is strictly concave then there exists a non-negative and possibly infinite function $\Delta(j,\pi)$ such that

(4.2) (1)
$$H(\pi) = \Sigma \pi_{j} \Delta_{H}(j, \pi) \quad \forall \pi \in S^{k}$$
 and

(4.3) (11)
$$H(\pi) = \Sigma \pi_{j} \Delta_{H}(j,\pi) \leq \Sigma \pi_{j} \Delta_{H}(j,\pi^{*})$$

for all π , $\pi^* \in S^k$, with equality only if $\pi = \pi^*$. The existence of Δ_H for every strictly concave function H is due to Haberman (1982), and it can be obtained as follows.

Let H^* be an extension of H to R_+^k such that $\Psi \alpha \ge 0$

(4.4)
$$H^{\dagger}(\alpha\pi) = \alpha H^{\dagger}(\pi).$$

Then for $\pi \in S^k$ with $\pi_j > 0$, $1 \le j \le k$, the penalty function $\Delta_H(j,\pi)$ is given by

is also expressed as (in analogy to variance decomposition) SST = SSW + SSB.

$$\Delta(j,\pi) = \frac{\partial}{\partial \pi_j} H^* \Big|_{\pi}.$$

In terms of the penalty function associated with a strictly concave function H the following decomposition of the total diversity $H(\pi_{\cdot})$ (or SST), obtained by Rao and Nayak (1985), allows an interpretation of the diversity between populations J_{H} (or SSB)

(4.6)
$$H(\pi_{\cdot}) = \Sigma \lambda_{\varrho} H(\pi_{\varrho}) + \Sigma \lambda_{\varrho} C_{H}(\pi_{\varrho}, \pi_{\cdot})$$

where

では、10mmによっている。 10mmによっている。 10mmによっている。

(4.7)
$$C_{\mathbf{H}}(\pi,\pi) = \sum_{j=1}^{k} \pi_{j} [\Delta_{\mathbf{H}}(j,\pi^{*}) - \Delta_{\mathbf{H}}(j,\pi)].$$

The function $C_{H}(*,*)$, called as the 'Cross-entropy' induced by H, is non-negative but not necessarily symmetric. A more general discussion can be found in Rao and Nayak (1985).

Since π_1, \ldots, π_r are associated with r levels of a factor X, the ratio

(4.8)
$$\rho_{H}^{2} = \frac{SSB}{SST} = \frac{\sum_{\ell} C_{H}(\pi_{\ell}, \pi_{\ell})}{H(\pi_{\ell})}$$

can be used as a measure of association between X and the response variable Y.

Now we give the extension H^* , and penalty function $\Delta(j,H^*)$ essentially needed to compute the cross-entropy (i.e. measure the dissimilarity between π and π^*) for the proposed diversity measures H_1 , H_2 and H_3 .

Extensions H_1^* , H_2^* and H_3^* satisfying the condition (20) are, Ψ $\pi \in \mathbb{R}_+^k$

(4.9)
$$H_{1}^{\star}(\pi) = \sum_{j=1}^{k} \pi_{j} [1 - a_{1}(\Sigma \pi_{k})^{\gamma} \{b_{1} \Sigma \pi_{k} - \pi_{j}\}^{-\gamma}]$$

(4.10)
$$H_{2}^{\star}(\pi) = \sum_{j=1}^{k} \pi_{j} [1 - a_{2} (\Sigma \pi_{\ell})^{\gamma} (b_{2} (\Sigma \pi_{\ell})^{\gamma} - \pi_{j}^{\gamma})^{-1}]$$

and

(4.11)
$$H_{3}^{*}(\pi) = \sum_{j=1}^{k} \pi_{j} \left[1 - a_{3}(\Sigma \pi_{\ell})^{\gamma} \left\{b_{3}(\Sigma \pi_{\ell})^{\gamma} + (\Sigma \pi_{\ell} - \pi_{j})^{\gamma}\right\}^{-1}\right]$$

where

$$b_1 = 1 + k^{-1}$$
, $b_2 = 2 - k^{-\gamma}$ and $b_3 = (1 - k^{-1})^{\gamma} = a_3$

the ' Σ ' represents $\sum_{\ell=1}^{K}$.

The penalty functions $\Delta_{\underline{H}_{\underline{m}}}$ induced by the functions $\underline{H}_{\underline{m}}$, according to (21), turn out to be, for $\underline{m} = 1, 2, 3$,

(4.12)
$$\Delta_{\underline{H}_{1}}(j,\pi) = \frac{a_{1}^{\gamma}\pi_{1}^{-}a_{1}^{b}}{(b_{1}^{-}\pi_{1}^{\gamma})^{\gamma+1}} + 1 - \sum_{\ell=1}^{k} \frac{\gamma a_{1}^{2}\pi_{\ell}^{2}}{(b_{1}^{-}\pi_{\ell})^{\gamma+1}}$$

(4.13)
$$\Delta_{H_{2}}(j,\pi) = \frac{a_{2}\tilde{\gamma}\pi_{1}^{\gamma} - a_{2}b_{2}}{(b_{2}-\pi_{1}^{\gamma})^{2}} + 1 + \sum_{\ell=1}^{k} \frac{\gamma a_{2}\pi_{\ell}^{\gamma+1}}{(b_{2}-\pi_{\ell}^{\gamma})^{2}}$$

(4.14)
$$\Delta_{\text{H}_{3}}(j,\pi) = \frac{\mathbf{a}_{3}(\tilde{\pi}_{j})^{-\tilde{\gamma}}(1+\tilde{\gamma}\tilde{\pi}_{j})-\mathbf{a}_{3}\mathbf{b}_{3}}{(\mathbf{b}_{3}-\tilde{\pi}_{j}^{\gamma})^{2}} + 1 + \sum_{\ell=1}^{k} \frac{\mathbf{a}_{3}\pi_{\ell}^{2}}{(\mathbf{b}_{3}-\tilde{\pi}_{\ell}^{\gamma})^{2}}$$

where $\tilde{\gamma} = 1-\gamma$ and $\tilde{\pi}_1 = 1-\pi_1$.

In the case $\gamma = 1$,

(4.15)
$$\Delta_{G_1}(j,\pi) = \frac{-k^{-1}(1+k^{-1})}{(1+k^{-1}-\pi_j)^2} + 1 - \sum_{\ell=1}^{k} \frac{k^{-1}\pi_\ell^2}{(1+k^{-1}-\pi_\ell)^2}$$

and

(4.16)
$$\Delta_{G_2}(j,\pi) = \Delta_{G_3}(j,\pi) = \frac{-(1-k^{-1})(2-k^{-1})}{(2-k^{-1}-\pi_1)^2} + 1 + \sum_{\ell=1}^k \frac{(1-k^{-1})\pi_\ell^2}{(2-k^{-1}-\pi_\ell^2)} .$$

Let us now consider the problem of testing the hypothesis H_0 : $\pi_1^{=\pi_2}$: $\pi_r^{=\pi_2}$... $\pi_r^{=\pi_1}$. Following Rao (1982,a,b), a test of this hypothesis can be based on J_H (i.e. SSB)

since under H_0 , $J_H = 0$ in the population and conversely $J_H = 0$ implies 1^{-1} provided H is strictly concave.

Based on a sample from a population P of the k-dimensional nominal r.v. Y divided into sub-samples according to r levels $(r \ge 2)$ of the factor X, we are going to propose a criteria, based on SSB, to test the null hypothesis that X and Y are independent, i.e. $H_0: \pi_1^{-\pi} \pi_2^{-\pi} \cdots \pi_r^{-\pi}$.

For the ith level of the factor X, i=1,2,...,r, let n_{ij} be the observed frequency for the jth category of Y, j=1,2,...,k, in a sample of size $n = \sum_{ij}^{n} n_{ij}$. Further let

(4.17)
$$n_{i} = \sum_{j} n_{ij}, \quad n_{,j} = \sum_{j} n_{ij}, \quad v_{i} = (n_{i1}, \dots, n_{ik})^{\dagger}$$

$$p_{i} = \frac{1}{n_{i}} v_{i} \quad \text{and} \quad p_{,,,} = \frac{1}{n_{,,}} \sum v_{i}$$

The total, within and between group diversities for the sample are

(4.18)
$$\hat{SST} = H(p_{..})$$

$$\hat{SSW} = \sum_{i=1}^{n} \frac{n_{i}}{n_{..}} H(p_{i})$$

and

Naik (1985) has shown that asymptotically, under H_0 , (i) SSB is distributed as a linear combination of independent χ^2 variables and (ii) SSB and SST are independently distributed. For the sake of completeness and for determining the critical region for testing H_0 , we give the basic assumptions and the main results of Naik (1985).

For a statistical analysis the sample vectors v_1 , i=1,2,...,r are assumed to be independently and multinomially distributed with parameters v_1 and

$$\pi_{i} = (\pi_{i_1}, \dots, \pi_{i_k})'$$

Let H^R be a non-negative, strictly concave and twice differentiable function defined on R_+^{k} satisfying the condition (20). Let

(4.19)
$$\nabla_{\mathbf{H}^{\star}}^{2}(\mathbf{x}) = \left(\left(\frac{\partial^{2}\mathbf{H}^{\star}(\pi)}{\partial \pi_{\mathbf{j}}, \partial \pi_{\mathbf{j}}}\right)\right)_{\pi=\mathbf{x}}^{\pi=\mathbf{x}}$$

be the matrix of second order derivatives of H^{*}. Then, under H₀: $\pi_1 = \pi_2 = \dots = \pi_r = \pi$ as $n_1 \to \infty$ and $\frac{n_1}{n_1} \to \lambda_1 > 0$, asymptotically,

[I]
$$2n...\hat{SSB} \sim -\sum_{j=1}^{k-1} \beta_j \chi_j^2(r-1)$$

where $\chi_j^2(r-1)$, $i=1,\ldots,k-1$ are i.i.d. χ^2 random variables with (r-1) d.f. and β_j , $j=1,2,\ldots,(k-1)$ are possible non-zero eigenvalues of

(4.20)
$$\nabla_{\mathbf{H}^{\pm}}^{2}(\pi) \cdot \mathbf{D}_{\pi} = \Delta_{\mathbf{H}^{\pm}}^{2} \quad (sey)$$

[II] SST and SSB are independently distributed.

For a proof of results (i) and (ii), see Naik (1985b).

For testing the null hypothesis that X and Y are independent, i.e. H_0 : π_1 =...= π_r against the general alternative, a natural criteria, based on analysis of diversity using a diversity measure H, would be to reject H_0 at level α , if $\hat{SSB} \geq c$, choosing c such that

(4.21)
$$P\{\hat{SSB} \geq c | H_0 \} = \alpha$$
.

The result [I] of Naik (1985), cited above, becomes useful for determining the critical value c. For each of the proposed, diversity measures H_m , m=1,2,3

we have computed the matrix $\Delta_{\text{H}^{\pm}}^2$, m=1,2,3 with the help of the extensions H_m^{\pm} given in (4.9), (4.10) and (4.11). Although in practice it is possible with the help of existing computer programme, to compute the eigenvalues of Δ_{\pm}^2 based on the estimate $\hat{\pi} = p...$, the following approximation for the asymptotic distribution of SSB can be used. Approximating the eigenvalues α_1 , i=1,2,...,k-1 by their average value

(4.22)
$$\overline{\beta}_{H^{*}} = \frac{1}{k-1} \sum_{j=1}^{k-1} \beta_{j}$$

$$= \frac{1}{k-1} \operatorname{Tr}(\Delta_{H^{*}}^{2}) = \frac{1}{k-1} \sum_{j=1}^{k-1} d_{jj}(\pi)$$

where

$$d_{jj}(x) = \frac{\partial^2}{\partial \pi_j^2} H^*(\pi) \Big|_{\pi=x} ,$$

the asymptotic distribution of 2n.. SSB can be approximated by the distribution of $-\bar{\beta}_{H} \star \chi^{2}(r-1)(k-1)$. Further, if the estimator

(4.23)
$$\hat{\beta}_{\mathbf{H}^{*}} = \frac{1}{k-1} \sum_{i=1}^{k} p_{i} d_{ii}(p_{i})$$

is a consistent estimator of $\overline{\beta}_{H^{\bigstar}}$, then we shall have

(4.24)
$$\frac{\overline{n..ssb}}{-\overline{\beta}_{H^{*}}} \sim \chi^{2}(r-1)(k-1),$$

see Naik (1985). Light and Margolin (1971) using Gini-Simpson index of diversity and Nayak (1984) using quadratic entropy of Rao, have found the above approximation useful.

The matrix $\Delta_{H_m^{\pm}}^2$ and the average eigenvalue $\overline{\beta}_{H_m^{\pm}}$ corresponding to each of the proposed diversity measures H_m , m=1,2,3, along with the elements of $\nabla_{H_m^{\pm}}^2$ are as follows.

For m=1,2,3 and $\pi \in S^k$, let

(4.25)
$$d_{m;jj}, = \frac{\partial^{2}}{\partial \pi_{j} \partial \pi_{j}}, H_{m}^{*}(\pi); \quad 1 \leq j, j' \leq k,$$

then, for m=1,

(4.26)
$$d_{1,jj} = a_1^{\gamma} \{ (2\pi^{-1})B_j (b_1^{-\pi})^{-\gamma-2} - S_1 \}$$

(4.27)
$$d_{1,jj} = a_1 \gamma \{ \pi_j B_j (b_1 - \pi_j)^{-\gamma - 2} + \pi_j B_j, (b_1 - \pi_j)^{-\gamma - 2} - S_1 \}$$

where

$$a_1 = k^{-\gamma}, b_1 = 1+k^{-1}$$
 $B_t = 2b_1 - (1-\gamma)\pi_t, \text{ and } S_1 = \sum_{\ell=1}^k \frac{\pi_\ell^2 B_\ell}{(b_1 - \pi_\ell)^{\gamma+2}}$

For m = 2

(4.28)
$$d_{2,jj} = a_{2}Y\{(2\pi_{j}-1)\pi_{j}^{Y-1}C_{j}(b_{2}-\pi_{j}^{Y})^{-3}-S_{2}\},$$

(4.29)
$$d_{2,jj}, = a_{2}^{\gamma} \{ \pi_{j}^{\gamma} c_{j} (b_{2} - \pi_{j}^{\gamma})^{-3} + \pi_{j}^{\gamma}, c_{j}, (b_{2} - \pi_{j}^{\gamma})^{-3} + c_{j} \}$$

where

$$a_2 = 1-k^{-\gamma}$$
, $b_2 = 2-k^{-\gamma}$
 $c_t = (1+\gamma)b_2 - (1-\gamma)\pi_t^{\gamma}$, and $s_2 = \sum \frac{\pi_{\ell}^{1+\gamma}c_{\ell}}{(b_2-\pi_{\ell}^{\gamma})^3}$

Finally for m = 3,

(4.30)
$$d_{3,jj} = a_{3}^{\gamma} \{ (2\pi_{j}^{-1}) \tilde{\pi}_{j}^{\gamma-2} D_{j} (b_{3}^{+} \tilde{\pi}_{j}^{\gamma})^{-3} - S_{3} \}$$

(4.31)
$$d_{3,jj}$$
, = $a_{3}Y\{\pi_{j}\tilde{\pi}_{j}^{Y-2}D_{j}(b_{3}+\tilde{\pi}_{j}^{Y})^{-3}+\pi_{j},\tilde{\pi}_{j}^{Y-2}D_{j},(b_{3}+\tilde{\pi}_{j},)^{-3}-s_{3}\}$

where

$$a_3 = (1-k^{-1})^{\gamma}, b_3 = (1-k^{-1})^{\gamma}, \tilde{\pi}_t = 1-\pi_t,$$

$$D_t = b_3(1+\gamma)\tilde{\pi}_t + (1+\gamma)\tilde{\pi}_t^{\gamma} + (1-\gamma)\tilde{\pi}_t^{1+\gamma} + b_3(1-\gamma)$$

and

$$s_3 = \sum_{\ell=1}^{k} \frac{\pi_{\ell}^2 \bar{\pi}_{\ell}^{\gamma-2} C_{\ell}}{1 (b_3 + \bar{\pi}_{\ell}^{\gamma})^3}.$$

With these computations, the matrix $\Delta_{H_{j}^{\pm}}^{2}$, for j=1,2,3 can be worked out as

(4.32)
$$\Delta_{\mathbf{H}_{\underline{m}}}^{2}(\pi) = ((\mathbf{d}_{\underline{m},jj},)) \cdot D_{\underline{m}},$$

(4.33)
$$\overline{\beta}_{H_{m}^{*}} = \frac{1}{k-1} \int_{j=1}^{k} \pi_{j} d_{m,jj},$$

Case $\gamma = 1$ For the diversity measures $G_1(\pi)$ and $G_2(\pi)$ (= $G_3(\pi)$) defined in (15), we have

(4.34) (1):
$$\Delta_{G_{1}^{+}}^{2}(\pi) = ((d_{jj},)) \cdot D_{\pi}$$

$$\overline{\beta}_{G_{1}^{+}} = \frac{1}{k-1} \sum_{j=1}^{k} d_{jj}$$

where

$$d_{jj} = 2a_1^*b_1^* \left[\frac{(2\pi_j - 1)}{(b_1^* - \pi_j)^3} - \sum \frac{\pi_\ell^2}{(b_1^* - \pi_\ell)^3} \right]$$

and

$$d_{jj'} = 2a_1^*b_1^* \left[\frac{\pi_j}{(b_1^* - \pi_j)^3} + \frac{\pi_{j'}}{(b_1^* - \pi_{j'})^3} - \sum \frac{\pi_{\ell}^2}{(b_1^* - \pi_{\ell})^3} \right]$$

where $a_1^* = k^{-1}$, $b_1^* = 1+k^{-1}$

(4.35) (ii):
$$\Delta_{G_2^{\hat{\pi}}}^2(\pi) = ((d_{jj}^*,)) \cdot D_{\pi}$$

where

$$d_{jj}^* = 2a_2^*b_2^*\left[\frac{(2\pi_1^{-1})}{(b_2^{-\pi_1})^3} - \Sigma \frac{\pi_\ell^2}{(b_2^{-\pi_\ell})^3}\right]$$

$$d_{jj}^{*} = 2a_{2}^{*}b_{2}^{*}\left[\frac{\pi_{j}}{(b_{2}^{*}-\pi_{j})^{3}} + \frac{\pi_{j}^{*}}{(b_{2}^{*}-\pi_{j})^{3}} - \sum \frac{\pi_{\ell}^{2}}{(b_{2}^{*}-\pi_{\ell})^{3}}\right]$$

$$a_2^* = 1-k^{-1}$$
, and $b_2^* = 2-k^{-1}$

(4.36) (i.i.):
$$\overline{\beta}_{G_m^*} = \frac{-a_m^* b_m^*}{k-1} \sum_{\ell=1}^k \frac{\pi_{\ell} (1-\pi_{\ell})}{(b_m^* - \pi_{\ell})^3}; m=1,2.$$

ACKNOWLEDGEMENTS

The author wishes to thank Professor B.K. Sinha and Professor Tapan Nayak for their helpful comments.

The problem of measuring diversity within populations and dissimilarity or similarity between populations has been extensively treated in the literature. In this context a general procedure called Analysis of Diversity has been outlined and examined by C.R. Rao in a series of papers.			
In this paper we propose three new measures of direlated inference problems.	versity and study Continued

Denote by S^k the simplex $S_m = \{\pi: x = (\pi_1, \dots, \pi_k)', \pi_j \geq 0, \Sigma \pi_j = 1\}$. Then the proposed measures are of the form: $H_m(\pi) = 1 - a_m \Sigma_j \pi_j \phi_m(\pi_j)$, m = 1, 2, 3 where $\phi_1(x) = (1 + k^{-1} - x)^{-\gamma}$, $\gamma \geq 0$, $\phi_2(x) = (2 - k^{-\gamma} - x^{\gamma})^{-1}$, $\gamma \geq 0$, $\phi_3(x) = (a_3 + (1 - x)^{\gamma})^{-1}$, $0 < \gamma \leq 1$, and the a's are suitable normalizing constants. Estimation of $H_m(\pi)$, derivation of the penalty function and cross entropy and the problem of testing independence have been treated. Asymptotic distributions of relevant test statistics are indicated.
